

GDGC Cloud Recruitment Problem

Statement 1: FIFA Pulse – Predict the Tournament

Background

The FIFA World Cup is approaching, and the **GDGC Sports Analytics Team** wants to launch an interactive prediction platform for football fans.

The platform will allow users to vote for which team they think will win upcoming matches. However, simply collecting predictions is not enough—the analytics team also wants insights into platform activity, user engagement, and system health.

As a **Cloud Infrastructure & Analytics Engineer**, your mission is to deploy the prediction platform and build a monitoring system that tracks its performance and usage.

Mandatory Tasks

1. Prediction Platform Setup

Create a FIFA prediction website that displays upcoming matches.

Requirements

- Display at least **5 upcoming FIFA matches**
 - Allow users to vote for the team they think will win
 - Display vote counts for each team
 - Store votes dynamically (avoid hardcoded values where possible)
-

2. Cloud Deployment

Deploy the prediction website on a free cloud hosting platform.

Requirements

- Public URL
 - HTTPS enabled
 - GitHub repository
 - Auto deployment preferred
-

3. Analytics Dashboard

Create a separate analytics dashboard (or page) that displays:

- Total votes cast
- Most voted team
- Total site visitors
- Request count
- Website uptime/status
- Timestamp of the last update

Requirements

- Dashboard may be hosted on a separate route or as a separate site
 - Data should update dynamically wherever possible
-

4. Basic Documentation

Submit a report containing:

- Deployment steps followed
 - Architecture overview
 - Cloud services/platforms used
 - Challenges faced
 - Screenshots of the working application
-

5. Repository Structure

Maintain a clean and organized project structure.

Example

FIFA-Pulse

- frontend
- backend
- analytics
- assets
- README.md
- screenshots

Bonus Tasks (Optional)

These tasks are **optional** and are intended for participants who want to explore beyond the fundamentals.

Real-Time Analytics

- Update analytics automatically without refreshing the page
- Display live vote activity

Monitoring & Logging

Add additional metrics such as:

- Average requests per minute
- Error count
- Peak traffic period
- Response time

Cloud Enhancements

- Add a custom domain
 - Create a custom 404 page
 - Implement a CI/CD pipeline
 - Containerize the application using Docker
-

Note

Bonus tasks are completely optional. We value understanding, problem-solving, and clarity of explanation more than simply completing every feature.

A simple, clean, and well-explained solution will always be preferred over a complex implementation that cannot be justified during discussion or interview.

Also, the design and complexity of the web pages themselves is not the judging criteria, but the architecture and deployment quality will determine your selectivity.

Submission Deliverables

Your submission should include the following:

- **Source Code**
 - A GitHub repository (or equivalent) containing your complete project.
- **Live Deployment**
 - Public URL of your deployed application.
 - Public URL of the analytics dashboard (if hosted separately).
- **Documentation**

Include a README or PDF describing:

 - Project overview
 - Technologies and cloud services used
 - Deployment process
 - Architecture overview
 - Any assumptions or challenges faced
- **Screenshots**

Screenshots demonstrating:

 - Prediction platform
 - Voting functionality
 - Analytics dashboard
 - Any bonus features (if attempted)
- **Bonus Tasks**

Include implementations and documentation for any optional tasks you completed.

Note: Ensure that all links are publicly accessible.

Important: Submit **one public link** containing all of the above deliverables. This may be a GitHub repository, a Google Drive folder, a Notion page, or any other platform, provided everything is organized and publicly accessible.
